.. is a multiplayer class in Counter-Strike: Global Offensive game. AHS Voiceroid Yuzuki Yukari V150 17. garmin unlock generator v.1.9 by jetmouse.rarQ: how to cross validate simple linear regression model? I want to cross validate a simple linear regression model where I would like to compare the model to a random sample of the data, rather than using a holdout or cross validation. Any suggestions on how to do this? I have a dataset where I know the response variable, independent variable and sample sizes. I also know the expected correlation coefficient of the relationship between the independent and dependent variables. How do I calculate the predicted response for new data? A: If it's just comparing with a holdout set, I would use something like a permutation test. You randomly assign the "real" response to each of the N subjects and then fit the model, giving you N predictions. Compare the actual response of each of those N subjects with the corresponding prediction. Repeat this N times and you will see how the prediction works out when you're predicting on real data as opposed to randomly generating from the model. A: If you know the response, you can compute the correlation between the predicted and actual values. You can then fit the model again after adjusting the parameters on the basis of a new set of predictions. As with many statistical models, the lack of correlation between the predictions and actual outcomes is likely because the relationship is nonlinear. This is especially true in your case given the linear relationship you estimated, so you would need to use a regression technique that can model nonlinear relationships. A simple example: say your original relationship is $y=x+0.5x^2$ and you model it with $y=0.45x+1.5x^2$, you could let your model predict y for a couple of new values of x and compare those to the actual response (which would now be outside of the original data range). The difference in the y predicted from the regression and the actual response could be interpreted as a confidence interval on how well the model is doing. If you were comparing multiple models (i.e., you wanted to do cross-validation) you could randomly permute response values for the subjects within a model to get the data for your new model. The permutation test would be a
