An audit is a process that helps you understand which security risks you are facing in your network. It is based on a series of checks, always based on a set of predefined criteria, that apply to the OS, applications, services and hardware of your computers. The more vulnerabilities that are detected, the more susceptible your network is to attacks. The application can be easily used to check a Windows workstation, for example, or it can audit an entire LAN for all the security risks that might compromise the confidentiality, integrity or availability of the shared resources of your network. The application can also be used to assess the security of computers in a heterogeneous network, in which case it scans all the workstations running on different operating systems and virtual machines.

4MOSAn Vulnerability Management - Basic Features: Intuitive, wizard-based interface Automatically checks workstations for vulnerabilities Takes a single entry Ensures: 1) Confidentiality; 2) Integrity; 3) Availability Reporting: Reports in multiple formats, from simple to the most complex Extremely easy to use (as a network administrator, a user or a typical client) SMS, email, and e-mail support Data security policy control Advanced: Allows you to define special modes (e.g. info, warning, urgent) Advanced auditing mechanisms: help you assess the security status of a computer workstation Schedules/cron jobs Additional features: Independent risk-based analysis of computer workstations Intuitive security policy management, which enables the administrator to control more precisely the workstations in the network Option to restrict access to computers in a workgroup License model: Single user mode or corporate wide usage Registration process included (a simple check is enough for the activation) Support for support licenses: regional, support and maintenance (from 10 to 100 users) Versions available: Vulnerability Management v2 Requirements 4MOSAn Vulnerability Management supports Windows XP and later. #4: Automate Quality of Service Before examining how to perform the integration described in this article, however, I want to pause for a moment and explain exactly what I mean by Quality of Service. Just like the subjects of Firewalls and IPSs, that are also discussed in this article, the quality of the service in a network has a major impact on the effectiveness of the network. Quality of service (QoS) is a technique employed in networking to ensure that a specific level of service is provided to a specific network traffic while other traffic is given a lower priority. This is similar to the 'traffic shaping' technology of modern firewalls. Unlike other approaches, QoS is designed to preserve the underlying network technology. Therefore it does not interfere with the system but helps to improve it. A network engineering plan is typically created by a network administrator who attempts to maximize the overall performance of the network. To do this, he/she has to establish a plan that allocates the available network resources among the different types of traffic. To maintain the level of service, and maximize the efficiency of the network, it is crucial that network services manage the level of importance or priority of the users in the network. In a huge network, a network administrator could have hundreds of applications with users who receive and

send data. Therefore, he/she has to classify these applications in order to provide the correct level of service to each type of traffic. In this article we will examine how to implement QoS on a Linux network. #4: Automate Quality of Service

4MOSAn Vulnerability Management is a free, robust and powerful vulnerability management application. It is suitable for all popular network operating systems and can be executed in a stand alone mode as well as in an interactive mode. It can be run from any folder and has no dependencies on other software. It is very easy to use and you can start using it in less than 10 minutes. It does not require any technical expertise. It has a customized GUI and a simple user interface. The '4MOSAn Vulnerability Management' program operates under Windows operating system. The program is free to use and the license key gives the user the full access. It checks multiple servers located in different security domains, both internal and external, and includes their traffic on port 25, SMTP and secure FTP. Multiple servers can be selected to operate on, as well as several Domains. Exports the results in excel format and compares external and internal servers.

Q: How can I use different log files for two different applications at the same time I have two applications A and B I'd like to log from A and B using different files respectively. How can I do this in code? A: if using .NET 4.0 you could do this:

```
static void Main(string[] args) { var a = new Application(); var a1 = new Application2(a); var b = new Application3(a); b.Start(); a1.Start(); Console.WriteLine("Press any key to exit..."); Console.ReadKey(); } public class Application : ApplicationBase { public Application(ApplicationBuilder builder) : base(builder) { } public void Start() { try { // Do some work to set up the logging var fromA = new FormMessageHandler("Log A"); var fromB = new Logger("Log B");
```

This vulnerability management tool can assess the risk workstations in your LAN are facing, identifying potential vulnerabilities that might be exploited. Relying on an advanced scanning agent, it can assess the risk workstations in your LAN are facing, identifying potential vulnerabilities that might be exploited. Scan individual hosts or entire LANs for vulnerabilities that pose risks The application decides upon vulnerabilities and risks based on a set of pre-defined criteria organized by severity For instance, the password strength and age or Windows security vulnerabilities are considered urgent while other operating system hotfixes and registry settings might be critical, or with a high, medium or low risk. You are prompted to choose the target, be it the local host, the entire LAN or a manual selection of workstations. Alternatively, you can enter specific hosts to analyze or instruct Vulnerability Management to check an entire IP range or list. Generate security reports and compare audit results 4MOSAn Vulnerability Management displays the IP and MAC address for each identified workstation, as well as the OS version, and the average ping response time. Additional information about each host, such as the workgroup it belongs to, a list of opened ports, registered users, and SMB shares, is also available. Once the scan is complete, the dashboard displays a suggestive graph that includes all the issues requiring your attention. All this information can be easily included in a complete or a summary report, which can be saved either in PDF or HTML format. Alternatively, you can create XML, DOC, and CSV files A neat option is the comparison report, which reveals improvements in the vulnerability status, providing a simple means for you to find out whether the security measures you took have had effects. Audit your network to find security weaknesses 4MOSAn Vulnerability Management can evaluate the security of computers in your network based on a set of carefully selected criteria and security policies. For each identified issue it offers fixing suggestions, helping you improve network security. It audits individual workstations or IP ranges and

displays conclusive statistical charts that enable you to check to what extent computers are vulnerable to outside attacks. A complete and easy-to-use tool for comprehensive vulnerability management, 4MOSA's Vulnerability Management provides solutions to both simple and complex scenarios, offering a complete coverage of all vulnerability types. DGA demonstrates the evolution of scanning approaches since its introduction in 1998; SysTest and Vulnerability Labs Enforcer offer enhanced functionality. Vulnerability Management has two components: Vulnerabilities Analysis and Risk Analysis. The first is mainly a set
